7 WO 92/02084 on February 6, 1992.

8 Technical Field

9 The present invention relates generally to computer
10 terminals and peripheral devices used for transmitting, receiving
11 and storing information and more particularly to a method and
12 apparatus for wireless connections between the computer terminals
13 and the peripheral devices.

14 Background Art

15 Computer terminals and peripheral devices are now used in
16 practically every aspect of life. Computer terminals come in all
17 shapes and sizes and vary greatly in terms of function, power and
18 speed. Additionally, the number of peripheral devices which can
19 be attached to the computer terminals is increasing. Many
20 peripheral devices exist such as printers, modems, graphics
21 scanners, text scanners, bar code scanners, magnetic card
22 readers, external monitors, voice command interfaces, external
23 storage devices, and so on.

24 Computer terminals and peripherals have become dramatically
25 smaller and more portable. Personal computers and peripherals
26 are small enough to sit on the desk at work. Smaller still are
27 lap top computers and notebook computers. There are computer

1 terminals which are small enough to be mounted in a vehicle such
2 as a delivery truck or on a fork lift. Still smaller are the
3 hand held terminals typically used for their portability features
4 where the user can carry the computer terminal in one hand and
5 operate it with the other.

6 Despite the reduction in computer size, the computer
7 terminal still must physically interface with the peripheral
8 devices. Thus, there must either be a cable running from one of
9 the computer terminal to each device or the computer terminal
10 must be docked with the device while the information transfer is
11 to take place.

12 In the office or work place setting, the physical connection
13 is typically done with cables. These cables pose several
14 problems. If there are many peripheral devices, there must be
15 many cables attached to the computer terminal. In addition to
16 the eyesore created by all of the cables, the placement of the
17 peripheral devices is limited by the length of the cable. Longer
18 cables can be used but they are costly and do not alleviate the
19 eyesore created by having cables running in all directions.
20 Additionally, there may be a limited number of ports on the
21 computer terminal thus limiting the number of peripherals that
22 can be attached.

23 Another problem exists when there are several computer
24 terminals which must share the same peripheral device such as a
25 printer. All of the computers must be hardwired to the printer.
26 As discussed above, long cables can fix this problem at least
27 from a physical connection perspective but there still remains a

1 protocol problem between the different computers. This problem
2 is especially severe when the various computers are of different
3 types such as a mixed environment of IBM's and Macintoshes.

4 In the smaller computer terminal setting, the hand-held
5 terminals and the portables, the cabling and connection problem
6 can be more severe and cumbersome. Peripheral devices such as
7 printers and scanners of all types have been reduced dramatically
8 in size to match the smallness of the computer terminals. A
9 notebook computer operator may wish to carry the computer and a
10 cellular phone modem in a briefcase. Similarly, an operator may
11 wish to have a hand-held computer terminal in one hand, a small
12 portable printer attached to his belt, and a bar code scanner in
13 the other hand. The smallness of the computers and peripherals
14 makes these demands possible but the required cabling makes these
15 demands costly, inconvenient and even dangerous.

16 Physically connecting the computer terminals and peripherals
17 severely reduces the efficiency gained by making the units
18 smaller. An operator must somehow account for all of the devices
19 in a system and keep them all connected. This can be very
20 inconvenient. In the notebook computer and modem example, the
21 operator may wish to have freedom to move around with the
22 computer but without the modem. He may, for example, wish to
23 work in various locations on a job sight and at various times
24 transmit or receive information via his modem. If the modem and
25 the computer are hard wired together, he must either carry the
26 modem with him at all time or connect it and then disconnect it
27 each time he wishes to use the modem. Similarly, the operator of

1 the hand held terminal, scanner and printer will have the feeling
2 of being all tied up while using the three devices simultaneously
3 when all three devices are connected with cables.

4 The physical connections created by cabling can be expensive
5 because cables frequently prove to be unreliable and must be
6 replaced frequently. In portable environments, cables are
7 subject to frequent handling, temperature extremes, dropping and
8 other physical trauma. It is not uncommon for the cables or the
9 connectors for the cables on the devices to need replacing every
10 three months or so. Additionally, all of the cabling can be
11 dangerous. An operator who is using, holding or carrying several
12 devices and feels all tied up is not just inconvenienced, he may
13 be severely limited in his mobility and flexibility as he moves
14 about the work area. This loss of mobility and flexibility
15 directly undercuts the entire reason for having small and
16 portable computers and peripheral devices and greatly increases
17 the likelihood of operator injury while using the computer and
18 peripheral devices.

19 Furthermore, as the cables wear out and break, which, as
20 mentioned, happens frequently, there are dangers which are
21 associated with the electrical current running through the
22 cables. If the cable or connectors break, the current could
23 shock the operator or create a spark which could cause a fire or
24 even an explosion in some work environments.

25 Attempts to alleviate or eliminate these problems have been
26 made but have not been greatly successful. One solution is to
27 incorporate a computer terminal and all of the peripherals into

1 one unit. However, this solution is unsatisfactory for several
2 reasons. The incorporation of many devices into one unit greatly
3 increases the size and weight of the unit. This is
4 counterproductive when the main reason for having small machines
5 is portability and ease of use. Furthermore, incorporating all
6 of the functions into one unit greatly reduces and, in most cases
7 eliminates, the flexibility of the overall system. A user may
8 only wish to use a terminal one time, but the next time may also
9 wish to use a printer, and then the following time may not want
10 the printer but want a bar code scanner. An all-incorporated
11 unit thus becomes either overly large because it must include
12 everything, or very limiting because it does not include
13 everything.

14 Another solution has been to set up Local Area Networks
15 (LAN's) utilizing various forms of RF communication. The LAN's
16 to date, however, have been designed for large scale wireless
17 communications between several computer terminals or between
18 several computer terminals and a host computer. These systems
19 have proven ineffective as a solution for communication between a
20 computer terminal and its peripherals. The primary problems have
21 been the cost, size and power consumption of these systems. The
22 systems are designed for long range RF communication and often
23 require either a licensed frequency or must be operated using
24 spread spectrum technology. Thus, these radios are typically
25 cost prohibitive and too large for convenient use with personal
26 computers and small peripheral devices. Additionally, the
27 protocol for communication between several computer terminals (as

1 opposed to a computer terminal and one or more peripheral
2 devices) is different and has not been addressed.

3 Thus, there is a need for an apparatus used to create a
4 short range personal local area network system for wireless
5 communications and connections between computer terminals and
6 their peripherals.

7 Disclosure of the Invention

8 The present invention relates generally to computer
9 terminals and peripherals and, more specifically, to an apparatus
10 for creating a wireless local area network between the computer
11 terminal and its peripherals. A small, relatively inexpensive
12 transceiver is attached to, either internally or externally, a
13 computer terminal and each peripheral device. The transceiver
14 device allows for wireless communication of data or information
15 between the computer terminal and the peripheral devices. A
16 microprocessor, located inside of the transceiver, controls the
17 flow of information flowing through the transceiver. A lower
18 power radio is used to transmit and receive information. The
19 microprocessor also controls the communication protocol used for
20 the computer terminal and each peripheral device.

21 An object of the present invention is to provide a wireless
22 personal local area network utilizing a low powered radio for
23 communication between a computer terminal and its peripheral
24 devices.

25 Another object of the present invention is to provide a
26 wireless personal local area network for computer terminals and
27 peripheral devices which is low cost, reliable and convenient to

1 use.

2 A further object of the present invention is to provide a
3 wireless personal local area network which eliminates the dangers
4 and inconveniences of hardwiring computer terminals and
5 peripheral devices together.

6 Another object of the present invention is to provide a
7 wireless personal local area network that eliminates
8 compatibility problems between computer terminals and peripheral
9 devices.

10 Still another object of the present invention is to provide
11 a wireless personal local area network which can selectively
12 address particular devices in the network.

13 Other objects, advantages, and novel features of the present
14 invention will become apparent from the following detailed
15 description of the invention when considered in conjunction with
16 the accompanying drawings.

17 / Brief Description of the Drawings

18 Fig. 1 is a block diagram of a transceiver unit built in
19 accordance with the present invention;

20 Fig. 2 is a block diagram of a computer system utilizing the
21 transceiver units of Fig. 1;

22 Fig. 3 is a diagrammatic illustration of a computer operator
23 using a computer system utilizing the transceiver units of the
24 present invention;

25 Fig. 4 is a diagrammatic illustration of a computer operator
26 using an arm mounted computer system utilizing the transceiver
27 units of the present invention; and
28

1 Fig. 5 is a block diagram of the idle sense protocol.

2 Best Modes for Carrying Out the Invention

3 Referring now to the drawings wherein like reference
4 numerals designate identical or corresponding parts throughout
5 the several views, Fig. 1 shows a transceiver (10) built in
6 accordance with the present invention. The transceiver (10) has
7 a radio unit (12) with an attached antenna (13). The radio unit
8 (12) is a low power radio which operates at a frequency of 27
9 Mhz, can transfer information in asynchronous form at a rate of
10 19.2K BPS and has a range of approximately 40 to 100 feet. The
11 benefit of using the 27 Mhz frequency is that it is an unlicensed
12 frequency band. However, many different frequency choices could
13 be made and these choices will naturally affect some of the other
14 performance characteristics.

15 An interface (15) connects the transceiver (10) to a
16 computer terminal or a peripheral device. Many different
17 interfaces (15) could be used and the choice will depend upon the
18 connection port of the device to which the transceiver (10) will
19 be attached. Virtually any type of interface (10) could be
20 adapted for use with the transceiver (10) of the present
21 invention. Common industry interface standards include RS-232,
22 RS-422, RS-485, 10BASE2 Ethernet, 10BASE5 Ethernet, 10BASE-T
23 Ethernet, fiber optics, IBM 4/16 Token Ring, V.11, V.24, V.35,
24 Apple Localtalk and telephone interfaces.

25 A microprocessor (20) is connected between the interface
26 (10) and the radio unit (12) and controls the information flow
27 between the radio unit (12) and the interface (15). The

1 microprocessor (20) also controls the communication protocol
2 between the computer terminal and all of the peripheral devices.

3 The protocol is software driven and is run by the
4 microprocessor (20). It controls when the radio unit (12)
5 transmits and receives data and the form of that data. By
6 allowing the communication protocol to modify the form of the
7 transmitted and received data, otherwise incompatible devices can
8 communicate with each other. The protocol will always check to
9 make certain that the device it wishes to transmit to is not
10 already being communicated with before it sends a signal.

11 In order to insure that the proper device is receiving the
12 information transmitted, each device has a unique address. The
13 transceiver (10) can either have a unique address of its own or
14 can use the unique address of the device to which it is attached.
15 The unique address of the transceiver can either be one selected
16 by the operator or system designer or one which is permanently
17 assigned at the factory such as an IEEE address. The address
18 (21) of the particular transceiver (10) is stored in the
19 microprocessor (20).

20 The transceivers built in accordance with the present
21 invention can use an IDLE SENSE protocol to control communication
22 between the various data devices. In an IDLE SENSE protocol
23 system, the data device, which will be called the base device,
24 with the greatest battery capacity will send IDLE SENSE messages
25 to the other data devices at pre-arranged times. The data device
26 need not be the computer terminal since it may be hand held and
27 not have an abundance of battery capacity. The best data device

1 may be a printer device which is worn on the belt and therefore
2 may have a larger battery capacity. Or the best device may be a
3 secondary display which is mounted to a vehicle of some sort
4 which can utilize the power of the vehicle.

5 The IDLE SENSE message could be an invitation to the other
6 data devices to send information if it has any or could indicate
7 it had a message for one or more of the other data devices. If
8 one of the other data devices has a message to send, it awaits an
9 IDLE SENSE message from the base unit, starts the data link
10 protocol, and then sends its message to any of the other units,
11 including the base unit and including more than one unit. The
12 base station monitors all of the traffic of the various signals
13 and will not send an IDLE SENSE message until the channel is
14 clear. If the other data device does not establish a
15 conversation on the first try, it will wait for the next signal
16 to try again.

17 Referring to Fig. 5, a block diagram (80) of a typical idle
18 sense protocol is shown. When a device has a message to send,
19 assuming it is not the base device, it waits for an idle sense
20 signal to be sent by the base device. When an idle sense signal
21 is received, the device executes some form of back-off protocol
22 to determine if it will actually attempt to transmit its message.

23 Back-off protocol prevents all devices from attempting to
24 transmit messages every time an idle sense signal is transmitted
25 by the base device. Several protocol strategies have been
26 developed for carrier sense multiple access (CSMA) systems and
27 include 1-persistent, nonpersistent and P-persistent. The CSMA

1 strategies or variations thereof could easily be adapted to work
2 in an idle sense protocol system.

3 If the back-off protocol determines that the device should
4 wait, the device goes back to the wait for idle sense signal and
5 starts over. If the protocol determines that the device should
6 transmit, the device attempts to transmit its message to another
7 device and simultaneously checks to see if there are any
8 transmission collisions. If there are, then the device must go
9 back to the wait for idle sense signal stage and wait for the
10 next signal. If there are no collisions, the device can finish
11 transferring its message to another device.

a 12 The idle sense and back-off protocol ^{help} ~~help~~ to reduce the
13 number of transmission collisions and also help to recover from
14 collisions which do occur. Furthermore, by having the idle sense
15 signals sent at predefined intervals, power consumption of all
16 devices can be reduced. If the device knows when an idle sense
17 signal might come, it only has to power up and listen at those
18 times. This can result in significant power savings if the
19 device does not have to be powered up between idle sense signals.

20 If the base unit drops out for any reason, protocol exists
21 for one of the other units to assume the role of the base unit.
22 This protocol can be, but is no limited to being, based upon the
23 other data device which has the highest battery capacity. If the
24 original base unit reappears, protocol exists to transfer the
25 duties of sending the IDLE SENSE messages back to the original
26 base unit.

27 If the other data devices do not detect the base unit
28

1 sending IDLE SENSE messages, those station capable of being
2 master will initiate sending IDLE SENSE messages. When a unit
3 sending IDLE SENSE messages hears another unit sending IDLE SENSE
4 messages, it will determine whether to continue to send IDLE
5 SENSE messages based upon the power capacity of the other unit
6 sending the messages. If the two units are of the same capacity,
7 the two units will determine which will continue as the base unit
8 on a predefined user priority and then by other such protocol ^{if} of
9 necessary.

10 Referring now to Fig. 2, a computer system (30) is shown
11 utilizing transceivers (10), labeled microlink's, for information
12 transfer between the computer terminal (31) and the peripheral
13 devices (32, 33 & 34). As can be seen, using the transceivers
14 (10) allows communication to occur between the computer terminal
15 (31) and each of the peripheral devices (32, 33 & 34) without the
16 need for hardwiring them together.

17 The transceivers (10) can be interchanged with other
18 transceivers (not shown) with different performance
19 characteristics. For example, the transceivers may operate on a
20 different radio frequency, may have a different data transfer
21 rate, or may modulate the radio frequency in a different method.

22 It is also possible for two peripheral devices to
23 communicate even in the absence of the computer terminal (31).
24 This could be useful in a wide variety of situations. For
25 example, an operator may wish to carry the computer terminal (31)
26 and scanner (34) far enough away such that communication by the
27 computer terminal (31) with the printer (32) and the modem (33)

1 is not possible. However, while away, additional instructions
2 might arrive via the modem (33) which could be directly printed
3 on the printer (32). The communication protocol of the
4 transceivers (10) could easily accommodate this situation and
5 allow the communication to take place directly from the modem
6 (33) to the printer (32) without the need for the computer
7 terminal (31).

8 Referring now to Fig. 3, an operator (50) is shown using a
9 computer system (55) which utilizes the transceivers built in
10 accordance with the present invention. The operator (50) is
11 shown with a hand held computer terminal (56), a hand held
12 scanner (57) and a printer (58). Each of the hand held terminal
13 (56), scanner (57) and printer (58) has an attached or internal
14 low powered transceiver for wireless communication between the
15 hand held terminal (56) and the printer (58) and scanner (57).

16 The hand held computer terminal (56) also contains a UHF or
17 spread spectrum communication radio. This allows the hand held
18 computer terminal to be simultaneously part of the personal local
19 area network which utilizes the low powered transceivers which
20 connects the hand held terminal (56) to the scanner (57) and the
21 printer (58) and to a larger, longer range network. The hand
22 held computer terminal (56) connects to the larger network by
23 communicating directly with a base station (59) of the larger
24 network.

25 Referring now to Fig. 4, a computer system (65) is shown
26 utilizing mobile, or portable, data devices. The computer
27 terminal (70) is strapped to the forearm of the operator. The

1 scanner (71) straps to the back of the hand of the user and is
2 triggered by pressing a button (73) with the thumb. The computer
3 terminal (70) and the scanner (71) each have a low powered
4 transceiver built in accordance with the present invention built
5 inside. A printer (72) can be attached to the belt of the user.
6 The printer (72) also has an internal transceiver built in
7 accordance with the present invention.

8 The computer system (65) will likely use the IDLE SENSE
9 message protocol for communication since all of the data devices
10 are mobile and battery power will be a valuable resource. The
11 base unit may be the printer module since it is attached to the
12 belt and is most likely to have the highest battery capacity.

13 The transceivers located within or attached to the data
14 devices need not all have the same range. In the computer system
15 (65) of Fig. 4, the computer terminal (70) and the scanner (71)
16 may have very short ranges of two meters or less while the
17 printer (72) may have a communication range which is considerably
18 longer. The printer need not necessarily have a longer range if
19 the computer system is to be used in isolation, however, if the
20 system is to be used as part of a larger network, it would
21 require one of the data devices to have a longer range. Since
22 the printer is likely to have the largest battery capacity, it is
23 logical, though not required that the longer range transceiver be
24 attached to it.
